5.2: Fractional Distillation A simple distillation is incapable of significant purification if the boiling points of the components are too close. When the difference in boiling points is less than 100 °C, a modification is necessary, namely insertion of a fractionating column between the distilling flask and three-way adapter.

Distillation is the process of separating components of a mixture based on different boiling points. Examples of uses of distillation include purification of alcohol, desalination, crude oil refining, and making liquefied gases from air. Humans have been using distillation since at least 3000 BC in the Indus valley.

Continuous distillation, a form of distillation, is an ongoing separation in which a mixture is continuously (without interruption) fed into the process and separated fractions are removed continuously as output streams. Distillation is the separation or partial separation of a liquid feed mixture into components or fractions by selective boiling (or evaporation) and condensation.
