Identify metamorphic rock samples based on texture and composition. Sedimentary Rocks Sedimentary rocks are composed of sediments, which are unconsolidated material produced by weathering and erosion or by chemical or biochemical precipitation. Sediments are converted to solid rock by the process of lithification, which involves the compaction, cementation and hardening of sediments.

The three types of rocks—igneous, sedimentary, and metamorphic—are all subject to processes that change one rock type into another. The images below show several types of rocks undergoing these processes. Just as evaporation and precipitation are processes that move water through the water cycle, igneous, sedimentary, and metamorphic rock-forming processes move rocks through the rock cycle.

## **Igneous, Sedimentary, and Metamorphic Rocks**

When sediment from igneous rocks is compacted and cemented, the sediment becomes sedimentary rock. Then, if sedimentary rocks are subjected to changes in temperature and pressure, the rocks may become metamorphic rocks. Under certain temperature and pressure conditions, the metamorphic rock will melt and form magma.

Metamorphic rocks typically have different mineral assemblages and different textures from their parent rocks (Figure 7.1) but they may have the same overall composition. Figure 7.1 Metamorphic rock (gneiss) of the Okanagan Metamorphic and Igneous Complex at Skaha Lake, B.C. The dark bands are amphibole-rich, the light bands are feldspar-rich.
