Using photogrammetry on digital x-ray images Photogrammetry is a technique where digital photographs are converted into 3D models. This method is becoming increasingly popular among archaeologists at NTNU Vitenskapsmuseet, as a way of documenting structures and whole excavation sites in three-dimensional models.

Photogrammetry is the science and technology of obtaining reliable information about physical objects and the environment through the process of recording, measuring and interpreting photographic images and patterns of electromagnetic radiant imagery and other phenomena.. Photogrammetry appeared in the middle of the 19th century, almost simultaneously with the appearance of photography itself.

In traditional photogrammetry as I know it, the camera is a passive sensor where light goes in the opening of the lens through the optics and hits a medium that is capable of sensing light. These internal parameters are modeled in order to project from the image plane into object space to create a 3D point using parallax between multiple images.

The photogrammetry equipment is a little bit simpler. It's something we've been working with extensively over the last year. We use a Nikon D800E camera, which is 36 megapixels, and a fixed 50-millimeter Nikkor f/1.4 lens. For this application, we do not really want to use zoom lenses.

An X-ray is a quick, painless test that produces images of the structures inside your body — particularly your bones. X-ray beams pass through your body, and they are absorbed in different amounts depending on the density of the material they pass through. Dense materials, such as bone and metal, show up as white on X-rays.
